material under investigation. Different series of rabbits showed a reaction of hemagglutination titer of 1:16 to 1:512. The titer in the surface shavings of the infected vaccines was found to be considerably lower than in the shavings of the deeper layers. Hemagglutinins were also found in the material taken from skin shavings of a ram and the heifer. Attempts were made to discover the vaccine virus by a reaction of hemagglutination in isolated mucous membrane of the pharynx, blood, and urine of vaccinated animals and children. In the materials obtained from the mucous membranes of the pharynx and the mouth in which smallpox elements developed, hemagglutinins in dilution 1:128 were found, while in those with cutaneous vaccination hemagglutinins were found in only inconsiderable quantities, and then in only part of the experimental animals (in infection of a large skin area). A reaction

hemagglutination test of the isolated pharynx, blood, and urine obtained from vaccinated children produced a negative result; in a group of revaccinated children 7 to 8 years of age, the virus in the isolated pharynx was found in dilution of 1:2 to 1:4 in 3 of 10 children beginning from the 2nd to the 20th day after the vaccination. On the basis of their observations the authors come to the conclusion about the inadequate sensitivity of RGA for the discovery of small numbers of the virus. With the aid of "RTGA" an accumulation of antivaccine antibodies in the sera of vaccinated rabbits, calves, and humans was established. On the 12th day after humans were revaccinated, the average titer of antibodies in the serum increased from 51.4 to 300.8.

Title : A Directed Alteration of Flexner Dysentery Strains so as
to Increase Immunogenicity.

Orig Pub : Vopr. Kraevoy patol. AN UzSSR; 1956, No 8, 3-10

Abstract : A strain of Flexner dysentery bacteria No 661, type V, of
weak virulence (1-2 billion microbial bodies per Dcl) and
immunogenicity (20-42% survival of immunized mice) was
cultivated on filtrates of broth cultures of highly immu-
nogenic and virulent strains of the same type. The viru-
lence of the "bred" strain was successfully considerably
diminished, and a variant with a lethal dose equal to 3-4
billion microbial bodies was obtained. Simultaneously
the immunogenicity was successfully increased

Card 1/2

Abs Jour : Ref Zhur - Biol., No 3, 1958, 9951

(up to 78 and 86% survival of immunized mice).
However, the acquired properties were retained for only 1
year, after which the virulence markedly increased and the
strain's immunogenicity decreased. A considerable number
of variants were obtained, distinguished from the initial
strain by their ability to decompose sucrose.

TITLE: The Determination of the Degree of Clearance of Cylinders of Two-Cycle Engines (Opredeleniye stepeni ochistki tsilindrov dvukhtaknykh dvigateley)

PERIODICAL: Avtomobil'naya promyshlennost', 1958, Nr 7, pp 8-12 (USSR)

ABSTRACT: An accurate calculation of the processes of the elimination of fuel combustion products and filling of the cylinders with scavenging air is still so difficult that several assumptions simplifying the calculation must be included. The article suggests the splitting up of the air current, breaking up the entire flow in the cylinder into elementary streams by aid of approximate graphical and grapho-analytical methods of hydrodynamics (Figures 1,2,3). This can be done by the approximate method devised by S.F. Aver'yanov. The theoretical models of the cylinders of the engines of the YaAZ-204 (Fig. 2) and the German Volkswagen (Fig. 4) are analyzed by this method. Diverse graphical and mathematical solutions are presented. There are 5 graphs, 2 diagrams and 4 Soviet references.

TITLE: Production of fiberglass-reinforced plastic products

SOURCE: Sudostroyeniye, no. 8, 1966, 63

TOPIC TAGS: fiberglass, reinforced plastic, plastic fabricating machinery

ABSTRACT: The authors describe the development of a unit for combination forming of cabin doors and heat control panels. The unit was produced at the Kherson Shipbuilding Plant and is composed of a pressing chamber and vacuum chamber (see figure). The pressing chamber is a welded dome-shaped cover equipped with an insulated jacket. The vacuum chamber has doors which are air-tight. A diaphragm is placed between the pressing and the vacuum chambers. This diaphragm does the actual pressing. The unit is heated by tubular electric

7

heaters. The working temperatures are from 20 to 180°C and are automatically controlled. The following components are used for the products: ¹⁵PN-3(VTU33122-60LSNKh) polyethylene resin, ASTT(6)C₂ and KhTK-1 glass fillers and PKhV-1 foam plastic filler. The filled dies are placed inside the chamber which is preheated to 80-90°C and hermetically sealed. The vacuum initially is set at 600-650 mm Hg and four atmospheres are allowed to pass through the pressure feed after 5 to 6 minutes. The vacuum becomes weaker over a period of 10 to 15 minutes. The entire process takes 30 to 40 minutes. After the molding operation is finished, the pressure in the upper chamber is reduced and the die casting mold is removed through the door. The shell is removed from the mold and filled with PKhV-1 filler after which the cover is glued on. The unit is then placed in a hydraulic press and held for 24 hours. Such doors are 2.5 times lighter than wooden doors and their production saves 12,350 rubles a year. Orig. art. has: 3 figures.

Title : The Treatment of Patients with Alopecia Areata and Total Alopecia with ACTH and Cortine

Orig Pub : Probl. endokrinol. i gormonoterapii, 1958, 4, No 2, 111-112

Abstract : Observations were conducted on 20 patients with alopecia areata and total baldness or seborrheic hair thinning. To 5 patients with total baldness, ACTH was introduced intramuscularly in the dose of 15-20 units each daily; 600-700 units per course. To the remaining 15 patients, cortin was introduced subcutaneously in the amount of 1 ml 3 times per week each; 20-40 injections per course of treatment. Clinical cure was noted in 8, improvement in 8; no result in 4 patients. In possible recurrences

TOPIC TAGS: ground survey, general construction, civil engineering

ABSTRACT: The surveyor's duties in fulfilling the stipulations of the regulations issued by the Ministry of Construction (Epiquesugyi Miniszterium) were discussed, insofar as they pertain to the surveying of residential plots. The official entities entitled to such surveying, the requirements for the surveys from a technical and official angle, the means of preparing the surveys, and the procedures for obtaining the building permits and registration certificates were discussed. The drawings that are to accompany the applications are governed by specific regulations; these were described. [JPRS]

The velocity of fall of mercury drops in a viscous medium. 1. A. E. Gostakaya and A. N. Frumkin. *Compt. rend. acad. sci. U.R.S.S.* 55, 131-6(1947)(in English); cf. *C.A.* 40, 3249, 6044. The velocity of fall of Hg drops, 0.4-0.5 mm. radius, in glycerol contg. 1-3% H₂O and Na₂SO₄ or KBr as electrolyte was detd., with suitable corrections by Faxen's formula for the effect of the vessel walls and the hydrodynamic interaction of the falling drops in the column. In the presence of dissolved O₂ and with a small elec. cond. the drops fell at a rate in agreement with Stokes' formula. The charge on the drops after a certain time of contact with a soln. contg. dissolved O₂ is independent of its initial value. After removal of dissolved O₂ by bubbling H₂ through the soln. for 20 hrs., the values of the ratio, α , the velocity of fall of the liquid drop, w , to that of the velocity of fall of a solid sphere, w_s , varies between 1.03 and 1.47, depending on the charge, and approaches 1.5 times the value of w_s at small charges. The addn. of surface-active agents, such as amyl and octyl alcs., did not cause any appreciable change in the form of the curves. Values calcd. by the theoretical equation derived, agreed with the observed values. A. F.

The potentials of falling drops. I. Bagotskaya and S. Frumkin (Inst. Phys. Chem., Acad. sci. U.S.S.R., Moscow). *J. Phys. Chem.* (U.S.S.R.) 21, 1023-43(1947) (in Russian). -Hg drops, 1.2 mm. in diam., were forced from a capillary and fell in a KBr soln. in glycerol 98.00, 11.01 2%. When still attached to the Hg in the capillary, they were polarized by means of an auxiliary electrode. The polarization altered their surface charge σ which was calcd. from $i = \sigma A$, i being the current carried by the drops and A the area of the Hg/soln. interface formed in 1 sec. The sedimentation potential E between the top and the bottom of the glycerol column was measured as a function of σ . In N KBr E was almost independent of σ at large pos. σ , became zero at very small neg. σ , and changed its sign at greater neg. σ values. In $0.01 N$ and $0.015 N$ KBr E showed a max. at small pos. σ and a min. (i.e., a max. of the neg. E) at small neg. σ values. These results were observed after air was displaced from the soln. by H_2 ; in the presence of O_2 , E was almost independent of σ because the charge on the falling droplet was detd. by the compn. of the soln. rather than by the original polarization. The E values increased when the concn. of KBr decreased and reached about 0.1 v., i.e., were much greater than the sedimentation potentials of

solid insulating particles. A simplified theory of the effect is given (Levich, *C.I.* 42, 2156a). It shows, e.g., that the potential difference between the back and the front of a falling Hg drop was as high as 0.4 v. The theory predicts, in agreement with the expl., that the max. of E occurs at $\sigma = (3\mu\epsilon)^{1/2}$, μ being the viscosity and ϵ the elec. cond. of the soln. J. J. Bikerman

The potential of falling [mercury] drops. A. Frumkin and I. A. Bagotskaya (Univ. Moscow). *J. Phys. & Colloid Chem.* 52, 1-11 (1948); cf. *C.A.* 41, 7202f. — In an O-free soln. of KBr and glycerol with a viscosity of 8-14 poises, Hg drops fall from a dropping-Hg electrode with a drop time of about 0.4 sec. at the rate of 1.0-1.2 cm./sec. The drops are polarized by an e.m.f. which is applied between the dropping-Hg electrode and a large Hg electrode in the same soln. The potential arising from the fall of the drops is measured against 3 Ag-AgCl₂ electrodes spaced along the path of the drops. It is shown that the tangential motion of the surface of falling drops displaces the charges of the double layer from the lower

to the upper end of the drop, giving rise to a p.d. between the two ends. For drops of radius 0.6 mm., viscosity of the soln. 13, and elec. cond. 4×10^{-9} , the p.d. between the lower and the upper ends of the drop reaches 0.4 v. Measurements of the p.d. between various points of a liquid column in which the drops are falling are in fair agreement with values expected theoretically. In accordance with the theory of Frumkin and Levich (*C.A.*, 40, 6044) with increase in the charge density the abs. value of the potential of falling drops first increases, reaches a max., and then drops off. It also follows from these measurements that the relaxation time of the elec. double layer at the Hg-soln. interface in glycerol is less than 2×10^{-7} sec. Otto H. Müller

Movement of liquid and solid metal particles in electrolyte solutions. V. Experimental test of the equations for movement of mercury drops in an electric field. I. A. Bagotskaya. *Zhur. Fiz. Khim.* 23, 1231-8(1949); cf. *C.A.* 42, 3678h, and Frankin and Levich, *C.A.* 42, 5355b.—Hg fell in drops (radius 0.036 cm.) through KBr solns. in glycerol (η 2.6-3.3 poises) at 21-22°. The drops during their formation were charged by current i , and the charge q was calcd. as i/A , A being the drop area formed in 1 sec. (about 2×10^{-4} sq. cm./sec.). The solns. were satd. with H_2 to avoid variation of η during descent. Along about 3 cm. of their path, the drops were subjected to a horizontal electrostatic field of 0.25-1.5 v./cm.; the field strength was detd. by Ag/AgBr sounders. From the horizontal deviation of the drops their mobility V in cm./sec. in the elec. field was calcd. When q varied between $+35$ and -30×10^{-8} coulomb/sq. cm. and the elec. cond. κ between 10^{-2} and 10^{-3} ohm $^{-1}$ cm. $^{-1}$, V roughly followed the equation $V = \kappa/(2\eta + q^2)$ (cf. *C.A.* 40, 3328g). V was ≈ 0 at a small neg. q (instead of at $q = 0$) presumably because some O_2 was still present in the soln. At low κ , the max. V was too small, presumably because the potential gradient over the diam. of the drop became of importance. The max. V was, e.g. 2.4, 9, and 22 for pos. Hg drops at $\kappa = 1.9 \times 10^{-2}$, 2.5×10^{-3} , and 10^{-3} , resp.; hence, it was about 10 4 times as great as electrophoretic mobilities. Pyridine and trimethylpyridine do not affect V ; naphthylamine (0.1 M) lowers V .
J. J. Bikerman

CA BAGUTSKAYA, I. A.

2

Rate of fall of mercury drops in viscous medium. I. A. Bagutskaya (Acad. Sci. U.S.S.R., Moscow). *Zhur. Fiz. Khim.* 34, 1-9(1960); cf. C.A. 42, 2825g.—Hg drops (radius $r = 0.036$ cm.) fell in a KBr soln. in glycerol ($\eta = 2.5$ poises). When the distance d between 2 consecutive drops was less than, say, $50r$, the rate u of fall increased with the ratio $r:d$; e.g., at $r:d = 0.12$, u sometimes was 1.15 u_0 (u_0 is the rate of fall of a single drop). When u_0/u , ($u_0 =$ the rate calcd. from Stokes' equation) was large (e.g. 1.47), u/u_0 was near 1 and sometimes even less than 1. The ratio u_0/u had a max. (about 1.4) when the drops carried a charge e of about 3×10^{-8} coulomb/sq. cm.; this max. was steep in 0.01 N KBr and shallow in 0.5 N KBr. The dependence of u_0/u on e is accounted for by the earlier theory. In an acidified (with HNO_3) 0.38 N $HgNO_3$ soln. in glycerol u_0/u was 1.37. This high velocity cannot be explained by the effect of e , which was about 7×10^{-8} ; there must have been transfer of Hg ions across the drop/soln. boundary. In 0.1 M $C_6H_5NH_2 + 0.7 N$ KBr in glycerol the greatest u_0/u was 1.24; surface-active substances reduce the tangential movements in the drop (as in suppressing polarographic max.) and hence increase the friction between drop and soln. $AmOH$, octyl alc., and $PhNH_2$ had less effect. The values of u_0/u , near 1 found by the previous experimenters, e.g., Silvey (*Phys. Rev.* 7, 106(1916)) were due to low elec. cond. of the medium and the presence of O and surface-active impurities. J. J. Bikerman

CA BHOCTONAH, I. A.

4

Mechanism of mercury oxidation in electrolyte solutions.
I. A. Bhoctonah (Acad. Sci. U.S.S.R., Phys.-Chem. Inst., Moscow). *Zhur. Fiz. Khim.* 25, 450-57(1951).—The soln. of Hg in 2 N H₂SO₄ in an atm. of O₂ proceeds through an electrochem. mechanism: O₂ + 2H⁺ + 2e → H₂O₂ (1) and Hg → Hg⁺ + e (2). This is shown by the following observations: (1) There is equivalence between the amt. of Hg dissolved and the amt. of H₂O₂ formed in soln.; this can be seen with the help of polarograms of the soln. which can be compared to polarograms obtained with synthetic solns. contg. equiv. amts. of Hg and H₂O₂. This is in agreement with some data of Kolthoff (*C.A.* 34, 6539^o). (2) The rate of soln. of Hg at a Hg electrode depends on the electrode potential and can be detd. from the kinetics of electrolytic reduction of O₂. The latter is investigated by means of polarization curves at a Hg electrode at conditions such that the reduction of O₂ is the only electrode reaction taking place.

The Influence of Surface Active Substances on the Penetration of Hydrogen into Iron and the Mechanism of the Hydrogen Over-Potential. I. A. Bagotskaya and A. N. Kravkin. (*Doklady Akademii Nauk S.S.S.R.*, 1953, 82, (8), 979-982). (In Russian). A study of the transfer of the hydrogen over-potential through an iron diaphragm with the simultaneous measurement of the amount of hydrogen diffused through it during cathodic polarization in solutions of pure 1N HCl and in the presence of an inhibitor (tetrabutylammonium sulphate with potassium bromide) is described. On additions of arsenic to the polarization cell in concentrations of 10^{-6} – 10^{-4} M, with and without the inhibitor, the change of potential under the influence of the diffusing hydrogen was not observed. This result is in opposition to the views expressed in the literature that the increased diffusion of hydrogen, observed in the presence of arsenic, is due to the slower removal of hydrogen from the diaphragm surface.—V. G.

AUTHORS: Oshe, A. I., Bagotskaya, I. A. SOV/ 76-32-6-29/46

TITLE: The Effect of Diffusing Atomic Hydrogen on the Hydrogen Excess Voltage η on Iron and Its Galvanic Coatings in Basic and Acid Solutions (Vliyaniye diffundiruyushchego atomarnogo vodoroda na perenapryazheniye vodoroda η na zheleze i nanesennykh na nego gal'vanicheskikh osadkakh v rastvore shchelochi i kisloty)

PERIODICAL: Zhurnal fizicheskoy khimii, 1958, Vol. 32, Nr 6, pp. 1379-1388 (USSR)

ABSTRACT: Investigations on the effect of an artificial increase of the concentration of atomic hydrogen at the electrode surface on the kinetics of its electrochemical separation may supply information on the mechanism of this reaction, which fact had already been observed by A. N. Frumkin (Ref 1). In the present paper the problem mentioned in the title was investigated in the case of galvanic copper and nickel depositions on iron and in 1n NaOH solutions, as well as on pure iron and on iron blanched with tin and mercury; it was also investigated in the case of galvanic depositions of tin, nickel and copper in 1n H₂SO₄ solutions, the method applied remaining the same as in an earlier paper. As may be seen

Card 1/3

The Effect of Diffusing Atomic Hydrogen on the Hydrogen Excess Voltage η on Iron and Its Galvanic Coatings in Basic and Acid Solutions SM/6-32-6-29/46

from an experimental part the authors used Armco iron; the graphically represented experiments in the NaOH solution show that η increases in the case of the nickel deposition with small cathode polarization under the action of diffusing hydrogen, and that it decreases with a higher one; in the case of galvanic copper depositions, however, η always increases. In the case of a treatment of the galvanic depositions with mercury these effects change, however. The investigations in sulfuric acid solutions in the case of pure iron, iron blanché with lead and the galvanic depositions tin and copper did not display any influence of the diffusing hydrogen on η , while in the case of iron blanché in mercury a smaller effect was observed; this may be explained by a higher velocity of reformation of the atomic hydrogen (as compared to the alkaline medium). In the explanations of the observed effects the works by Gerischer and Mehl (Refs 8,9) are mentioned and it is pointed out that the dependence on the electrode polarization could not be taken into account. In order to obtain a comparison of the theoretical derivations with the experiment the influence of the amperage of the diffusing hydrogen i' on η

Card 2/3

The Effect of Diffusing Atomic Hydrogen on the Hydrogen Excess Voltage η on Iron and Its Galvanic Coatings in Basic and Acid Solutions DV/76-32-6-29/46

in the case of an electrode polarization with constant amperage was carried out, and it was found that in the beginning there is an increase which later on converges to a certain value, or that the decrease of the excess-voltage grows in the beginning and then approaches a limit value in the case of a polarization increase with constant i'/i . The observed effects of the decrease of the excess voltage were greater than those calculated theoretically. Finally the authors thank A.N. Frumkin, Member, Academy of Sciences, USSR. There are 9 figures and 9 references, 6 of which are Soviet.

TITLE: Study of the Effect of Diffusing Atomic Hydrogen on the Kinetics of Its Electrochemical Evolution

PERIODICAL: Zhurnal fizicheskoy khimii, 1960, Vol. 34, No. 7, pp. 1508-1516

TEXT: The effect of hydrogen diffusion on the kinetics of its electrochemical evolution was studied in Refs. 1-4 using an iron membrane fixed between two vessels and sealed with vacuum grease. Since a disturbing effect of the vacuum grease on the overvoltage η was suspected, the authors repeated their experiments with a new device shown in Fig. 1. A dish made of Armco iron (2 cm in diameter; about 1 cm high; wall thickness: 0.1 to 0.07 mm) was connected to a platinum contact by means of an iron clamp. The outside surface of the dish was polarized, and the inside surface was exposed to diffusion. Cell 1 contained hydrogen gas. The dish was filled from containers 2 and 3 with 1 N NaOH saturated with H₂ to a height of 2 to 3 mm. The inside surface of the dish was cathodically polarized with

Card 1/4

the platinum anode 4, and the diffusion potential φ_d was measured with respect to the reference anode 5. As soon as φ_d had reached a constant value, 2 N H_2SO_4 saturated with H_2 and containing traces of $Pb(NO_3)_2$ was pumped from container 8 into cell 1 such that it touched the bottom of the dish. The dish was temporarily polarized anodically. Hydrogen diffusion was discontinued by using hydrogen-saturated NaOH from container 11 instead of the acid solution. These experiments were performed with pure Armco iron, mercury-poisoned iron, and zinc-plated iron. The results were in agreement with the ones obtained previously. Overvoltage η was increased on non-poisoned iron and lowered on Hg-poisoned iron by hydrogen diffusion. The increase in Δi of the rate of electrochemical hydrogen evolution in the presence of diffusing atomic hydrogen was determined on Hg-poisoned iron and zinc-plated iron with $\eta = \text{const}$. For a given rate of diffusion i' , the amperage i was measured. For $\Delta i/i'$, the following values were found:

Moreover, the effect of i' , of the cathodic polarization of the electrode, and of the pH of the solution on $\Delta\eta$ was examined on Armco iron and nickel-plated iron. With constant cathodic polarization of the electrode $\Delta\eta$ increased with i' and approached a limit. Increase of η and decrease of pH led to a decrease of $\Delta\eta$. A. N. Frumkin is thanked for a discussion. There are 7 figures, 1 table, and 6 Soviet references.

Effect of the solution composition on the rate of diffusion of electrolytic hydrogen through metal diaphragms. I. Diffusion of hydrogen through iron diaphragms

PERIODICAL:

Zhurnal fizicheskoy khimii, v. 36, no. 12, 1962, 2667 - 2673

TEXT:

The time dependence of H₂ diffusion through an iron diaphragm was measured for the following solutions: 2 N NaOH, 2 N H₂SO₄, 2 N H₂SO₄ + 0.1 N KI, and 2 N H₂SO₄ + 0.1 N KI + 0.1 M (C₄H₉)₄NI. The diffusion side of the diaphragm was poisoned with As, Pb, or Hg, and cathodically polarized with 4·10⁻⁴ a/cm². Results: The presence of any of these solutions, and poisoning, on the diffusion side, with As in acid or alkaline media, Pb in acid, or Hg in alkaline media, reduces the diffusion rate v_H considerably. The opposite occurs with the same factors on the polarization side. Fe poisoned with Pb in alkali or with Hg in an acid does not follow this rule. The recombination theory developed by N. I. Kobozev and V. V. Monblanova

(Zh. fiz. khimii, 6, 308, 1935) according to which the binding energy and hydrogen are the decisive factors in diffusion, does not adequately explain the experimental results. Two processes are assumed to take place on hydrogen diffusion: hydrogen penetration of the metal during discharge, and its withdrawal into the solution by electrochemical desorption. These reactions are independent and probably occur on different parts of the diaphragm surface. The results obtained would then be explained by the relative value of changes in the activation energies of these reactions, and no definite dependence is necessary for the binding energy and over-voltage. There are 5 figures and 1 table.

TITLE:

Effect of the composition of the solution on the diffusion rate of electrolytic hydrogen through metal diaphragms. II. Hydrogen diffusion through palladium diaphragms.

PERIODICAL:

Zhurnal fizicheskoy khimii, v. 37, no. 1, 1963, 161 - 168

TEXT: The separate and combined effect of the I^- and $(C_4H_9)_4N^+$ ions on the hydrogen diffusion through Pd diaphragms was studied in 1 N H_2SO_4 (a), 1 N H_2SO_4 + 0.03 N KI (b), 1 N H_2SO_4 + $5 \cdot 10^{-3}$ M $[(C_4H_9)_4N]_2SO_4$ (c), and 1 N H_2SO_4 + 0.03 N KI + saturated $(C_4H_9)_4NI$ (d) solutions with and without addition of Hg. After pretreatment of the diaphragm in (a) with $2 \cdot 10^{-3}$ a/cm² current, the polarization was stopped at the diffusion side and continued with $5 \cdot 10^{-3}$ a/cm² current at the polarization side until a constant H_2 diffusion rate was established. The potential at the diffusion side was 50 - 60 mv. About half of the H_2 forming diffused through the diaphragm.

Effect of the composition ...

S/076/63/037/001/016/029
B144/B186

The effect of additions and Hg-poisoning of the diaphragm was studied in cathodic polarization, the respective current strengths being $i_{pol} = 5 \cdot 10^{-3} \text{ a/cm}^2$ and $i_{dif} = 0$. If I^- and Hg are introduced at the polarization side they increase the diffusion rate v_{dif} , whereas introduction at the diffusion side has the contrary effect. On KI addition at the polarization side, the overvoltage η increased to $\sim 80 \text{ mv}$ and $5/6$ of the hydrogen formed diffused through the diaphragm. This is in agreement with the negative effect of I^- and Hg on the energy of the metal - H_{ads} bond and on the hydrogen overvoltage retarding the discharge and removal of the adsorbed H. In further tests the action of I^- on v_{dif} and η was investigated after the electrode had been kept for some time in (b) without cathodic polarization. Here η increased steadily while v_{dif} decreased. This observed inconsistency implies the probable existence of two types of Pd poisoning by I^- : a weak type with increasing v_{dif} and η , in which only the active centers of the Pd surface take part in the hydrogen discharge
